

# General conception of derivative

Petr Lachout

May 18, 2011

# Differentiability of a function

Consider a function  $f : \mathbb{D} \rightarrow \mathbb{R}^m$ , where  $\mathbb{D} \subset \mathbb{R}^n$ .

Then, the derivative of  $f$  at a point  $\mathbf{x} \in \mathbb{D}$  in a direction  $\mathbf{h} \in \mathbb{R}^n$  is defined by

$$f'(\mathbf{x}; \mathbf{h}) = \lim_{t \rightarrow 0} \frac{1}{t} (f(\mathbf{x} + t\mathbf{h}) - f(\mathbf{x})), \text{ whenever the limit exists.}$$

Let us denote  $\mathbb{D}'_{\mathbf{x}} = \{\mathbf{h} \in \mathbb{R}^n : f'(\mathbf{x}; \mathbf{h}) \text{ exists}\}$ . Hence,

- ▶  $\mathbb{D}'_{\mathbf{x}}$  is a double-cone, i.e.  $\alpha\mathbf{h} \in \mathbb{D}'_{\mathbf{x}}$  whenever  $\alpha \in \mathbb{R}$  and  $\mathbf{h} \in \mathbb{D}'_{\mathbf{x}}$ .
- ▶ The function  $f'(\mathbf{x}; \cdot)$  is homogeneous on  $\mathbb{D}'_{\mathbf{x}}$  (a double-cone function), i.e.  $f'(\mathbf{x}; \alpha\mathbf{h}) = \alpha f'(\mathbf{x}; \mathbf{h})$  for each  $\alpha \in \mathbb{R}$ ,  $\mathbf{h} \in \mathbb{D}'_{\mathbf{x}}$ .
- ▶ For each  $\mathbf{h} \in \mathbb{D}'_{\mathbf{x}}$  there is an  $\delta > 0$  such that  $\mathbf{x} + t\mathbf{h} \in \mathbb{D}$  for all  $t \in [-\delta, \delta]$ .

# Differentiability of a function

- ▶ Function  $f$  is called **differentiable** at a point  $x \in \mathbb{D}$  if  $f'(x; h)$  exists for each  $h \in \mathbb{R}^n$ .
- ▶ Function  $f$  is called **Gâteaux differentiable** at  $x \in \mathbb{D}$  if  $f$  is differentiable at  $x$  and  $f'(x; \cdot)$  is a continuous linear function on  $\mathbb{R}^n$ .
- ▶ Function  $f$  is called **Hadamard differentiable** at  $x \in \mathbb{D}$  if  $f$  is differentiable at  $x$  and  $f'(x; \cdot)$  is a linear function on  $\mathbb{R}^n$  fulfilling

$$\lim_{n \rightarrow +\infty} \frac{1}{t_n} (f(x + t_n h_n) - f(x)) = f'(x; h)$$

for all sequences  $t_n \in \mathbb{R}$ ,  $t_n \neq 0$ ,  $h_n \in \mathbb{R}^n$ ,  $x + t_n h_n \in \mathbb{D}$ ,  
 $\lim_{n \rightarrow +\infty} t_n = 0$  and  $\lim_{n \rightarrow +\infty} h_n = h \in \mathbb{R}^n$ .

# Differentiability of a function

- ▶ Function  $f$  is called **boundedly differentiable** at  $x \in \mathbb{D}$  being differentiable at  $x$  and fulfilling

$$\lim_{t \rightarrow 0} \sup_{\substack{h \in \mathbb{R}^n, \|h\|=1 \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x+th) - f(x)) - f'(x; h) \right\| = 0.$$

- ▶ Function  $f$  is called **Fréchet differentiable** at  $x \in \mathbb{D}$  being Gâteaux differentiable at  $x$  and fulfilling

$$\lim_{t \rightarrow 0} \sup_{\substack{h \in \mathbb{R}^n, \|h\|=1 \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x+th) - f(x)) - f'(x; h) \right\| = 0.$$

# Counterexample

Consider a homogeneous function  $g$  on  $\mathbb{R}^n$ . Then,

$$\forall t \neq 0 \forall h \in \mathbb{R}^n \quad \frac{1}{t} (g(th) - g(0)) = \frac{1}{t} g(th) = g(h)$$

Hence,  $g'(0; h) = g(h)$  for each  $h \in \mathbb{R}^n$ . Thus,  $g$  is boundedly differentiable at the origin.

Particularly,

$$\begin{aligned} F(x_1, x_2) &= 0 \quad \text{whenever } x_2 \neq 0, \\ &= x_1 \quad \text{whenever } x_2 = 0. \end{aligned}$$

$F$  is homogenous, therefore, it is boundedly differentiable at the origin. But,  $F$  is discontinuous and, hence, its derivative at origin  $F'(0; \cdot) = F$  is discontinuous.

Bounded, Fréchet and Hadamard differentiability possess useful equivalent descriptions.

- ▶ Function  $f$  is **boundedly differentiable** at  $x \in \mathbb{D}$  if and only if it is differentiable at  $x$  and fulfills

$$\lim_{t \rightarrow 0} \sup_{\substack{h \in B \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x+th) - f(x)) - f'(x; h) \right\| = 0$$

for each bounded set  $B \subset \mathbb{R}^n$ .

- ▶ Function  $f$  is **Fréchet differentiable** at  $x \in \mathbb{D}$  if and only if it is Gâteaux differentiable at  $x$  and fulfills

$$\lim_{t \rightarrow 0} \sup_{\substack{h \in B \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x+th) - f(x)) - f'(x; h) \right\| = 0$$

for each bounded set  $B \subset \mathbb{R}^n$ .

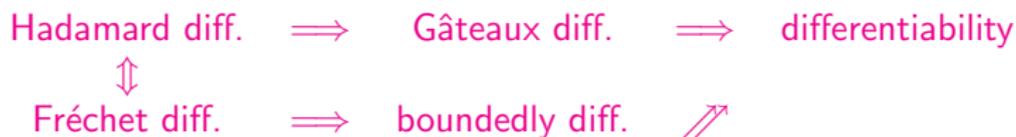

- ▶ Function  $f$  is **Hadamard differentiable** at  $x \in \mathbb{D}$  if and only if it is Gâteaux differentiable at  $x$  and fulfills

$$\lim_{t \rightarrow 0} \sup_{\substack{h \in K \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x+th) - f(x)) - f'(x; h) \right\| = 0$$

for each compact  $K \subset \mathbb{R}^n$ .

# Differentiability of a function

In finite dimension we have the following scheme:

If  $f$  is Gâteaux, Hadamard or Fréchet differentiable then the gradient

$$\nabla f(\mathbf{x}) = \begin{pmatrix} \frac{\partial f_1}{\partial x_1}(\mathbf{x}) & \cdots & \frac{\partial f_m}{\partial x_1}(\mathbf{x}) \\ \vdots & \ddots & \vdots \\ \frac{\partial f_1}{\partial x_n}(\mathbf{x}) & \cdots & \frac{\partial f_m}{\partial x_n}(\mathbf{x}) \end{pmatrix}$$

possesses the property

$$f'(\mathbf{x}; \mathbf{h}) = \nabla f(\mathbf{x})^\top \mathbf{h}.$$

# Directional differentiability of a function

Consider again a function  $f : \mathbb{D} \rightarrow \mathbb{R}^m$ , where  $\mathbb{D} \subset \mathbb{R}^n$ . Then, the directional derivative of  $f$  at a point  $x \in \mathbb{D}$  in a direction  $h \in \mathbb{R}^n$  is defined by

$$f'_+(x; h) = \lim_{t \rightarrow 0^+} \frac{1}{t} (f(x + th) - f(x)), \text{ whenever the limit exists.}$$

Let  $\mathbb{D}'_{x+} = \{h \in \mathbb{R}^n : f'_+(x; h) \text{ exists}\}$  denote the definition region of  $f'_+(x; \cdot)$ .

Hence,

- ▶  $\mathbb{D}'_{x+}$  is a cone, i.e.  $\alpha h \in \mathbb{D}'_{x+}$  whenever  $\alpha \geq 0$  and  $h \in \mathbb{D}'_{x+}$ .
- ▶ The function  $f'_+(x; \cdot)$  is positively homogeneous on  $\mathbb{D}'_{x+}$  (a cone function), i.e.  $f'_+(x; \alpha h) = \alpha f'_+(x; h)$  for each  $\alpha \geq 0$ ,  $h \in \mathbb{D}'_{x+}$ .
- ▶ For each  $h \in \mathbb{D}'_{x+}$  there is an  $\delta > 0$  such that  $x + th \in \mathbb{D}$  for all  $t \in [0, \delta]$ .

# Directional differentiability of a function

- ▶ Function  $f$  is called **Gâteaux directionally differentiable** at a point  $x \in \mathbb{D}$  if  $f'_+(x; h)$  exists for each  $h \in \mathbb{R}^n$ .
- ▶ Function  $f$  is called **Hadamard directionally differentiable** at  $x \in \mathbb{D}$  if  $f$  is Gâteaux directionally differentiable at  $x$  and

$$\lim_{n \rightarrow +\infty} \frac{1}{t_n} (f(x + t_n h_n) - f(x)) = f'_+(x; h)$$

for all sequences  $t_n > 0$ ,  $h_n \in \mathbb{R}^n$ ,  $x + t_n h_n \in \mathbb{D}$ ,  $\lim_{n \rightarrow +\infty} t_n = 0$  and  $\lim_{n \rightarrow +\infty} h_n = h \in \mathbb{R}^n$ .

- ▶ Function  $f$  is called **Fréchet directionally differentiable** at  $x \in \mathbb{D}$  being Gâteaux directionally differentiable at  $x$  and fulfilling

$$\lim_{t \rightarrow 0+} \sup_{\substack{h \in \mathbb{R}^n, \|h\|=1 \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x + th) - f(x)) - f'_+(x; h) \right\| = 0.$$

Requirement of continuous linearity is removed from the definition of Gâteaux directional differentiability.

### Proposition

*If a function  $f$  is Hadamard directionally differentiable at  $x$  then  $f'_+(x; \cdot)$  is a continuous function.*

# Counterexample

Consider a positively homogeneous function  $g$  on  $\mathbb{R}^n$ . Then,

$$\forall t > 0 \forall h \in \mathbb{R}^n \quad \frac{1}{t} (g(th) - g(0)) = \frac{1}{t} g(th) = g(h)$$

Hence,  $g'_+(0; h) = g(h)$  for each  $h \in \mathbb{R}^n$ . Thus,  $g$  is Fréchet directionally differentiable at the origin.

Particularly,

$$\begin{aligned} F(x_1, x_2) &= 0 \quad \text{whenever } x_2 \neq 0, \\ &= |x_1| \quad \text{whenever } x_2 = 0. \end{aligned}$$

$F$  is positively homogenous, therefore, it is Fréchet directionally differentiable at the origin. But,  $F$  is discontinuous and, hence, its directional derivative at origin  $F'_+(0; \cdot) = F$  is discontinuous.

Fréchet and Hadamard directional differentiability possess useful equivalent definitions.

- ▶ Function  $f$  is **Fréchet directionally differentiable** at  $x \in \mathbb{D}$  if and only if it is Gâteaux directionally differentiable at  $x$  and fulfills

$$\lim_{t \rightarrow 0^+} \sup_{\substack{h \in B \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x+th) - f(x)) - f'_+(x; h) \right\| = 0$$

for each bounded set  $B \subset \mathbb{R}^n$ .

- ▶ Function  $f$  is **Hadamard directionally differentiable** at  $x \in \mathbb{D}$  if and only if it is Gâteaux directionally differentiable at  $x$ ,  $f'_+(x; \cdot)$  is a **continuous** function and fulfills

$$\lim_{t \rightarrow 0^+} \sup_{\substack{h \in K \\ x+th \in \mathbb{D}}} \left\| \frac{1}{t} (f(x+th) - f(x)) - f'_+(x; h) \right\| = 0$$

for each compact  $K \subset \mathbb{R}^n$ .

# Directional differentiability of a function

In finite dimension we have the following scheme:

**Hadamard dir. diff.** possesses **continuous** directional derivative.

There is no linearity. Thus, we have **no** reasonable equivalent to **gradient**.

# Hadamard differentiability tangentially to a set

The concept of directional differentiability is limited by the assumption that  $f'_+(x; h)$  must exist for all  $h \in \mathbb{R}^n$ . With intention to relax the requirement, the concept of Hadamard directional differentiability tangentially to a set was developed, cf. [5], [3]. Unfortunately, the definition slightly differs due book to another. Therefore, we present a definition covering both of them.

# Hadamard differentiability tangentially to a set

We define the **Bouligand tangent cone**  
(also **contingent cone**, **Bouligand contingent cone**)  
to  $A \subset \mathbb{R}^n$  at  $x \in \mathbb{R}^n$  by

$$\mathbb{T}(x; A) = \left\{ h \in \mathbb{R}^n : \begin{array}{l} \text{there is a sequence } a_n \in A, t_n > 0, \\ \lim_{n \rightarrow +\infty} t_n = 0, \lim_{n \rightarrow +\infty} \frac{1}{t_n}(a_n - x) = h \end{array} \right\}.$$

The contingent cone is the **limsup in Kuratowski sense**

$$\mathbb{T}(x; A) = K\text{-}\limsup_{t \rightarrow 0^+} \frac{1}{t}(A - x).$$

# Hadamard differentiability tangentially to a set

$\mathbb{G} \subset \mathbb{D} \subset \mathbb{R}^n$ ,  $\mathbb{H} \subset \mathbb{R}^n$  be sets and  $f : \mathbb{D} \rightarrow \mathbb{R}^m$  be a function.

- Function  $f$  is called **Hadamard directionally differentiable** at  $x \in \mathbb{D}$  **tangentially** to  $(\mathbb{G}, \mathbb{H})$  if there is a function  $f'_H(x, \cdot; \mathbb{G}, \mathbb{H}) : \mathbb{T}(x; \mathbb{G}) \cap \mathbb{T}(x; \mathbb{H}) \rightarrow \mathbb{R}^m$  fulfilling

$$\lim_{n \rightarrow +\infty} \frac{1}{t_n} (f(x + t_n h_n) - f(x)) = f'_H(x, h; \mathbb{G}, \mathbb{H})$$

for all sequences  $t_n \in \mathbb{R}$ ,  $t_n > 0$ ,  $h_n \in \mathbb{R}^n$ ,  $x + t_n h_n \in \mathbb{G}$ ,  $\lim_{n \rightarrow +\infty} t_n = 0$  and  $\lim_{n \rightarrow +\infty} h_n = h \in \mathbb{T}(x; \mathbb{H})$ . (Of course,  $h \in \mathbb{T}(x; \mathbb{G})$  according to the definition of the contingent cone.)

- Function  $f$  is called Hadamard differentiable at  $x \in \mathbb{D}$  tangentially to  $(\mathbb{G}, \mathbb{H})$  being Hadamard directionally differentiable at  $x \in \mathbb{D}$  tangentially to  $(\mathbb{G}, \mathbb{H})$  and if  $\mathbb{T}(x; \mathbb{G}) \cap \mathbb{T}(x; \mathbb{H})$  is a double-cone and  $f'_H(x, -h; \mathbb{G}, \mathbb{H}) = -f'_H(x, h; \mathbb{G}, \mathbb{H})$  for all  $h \in \mathbb{T}(x; \mathbb{G}) \cap \mathbb{T}(x; \mathbb{H})$ .

# Hadamard differentiability tangentially to a set

Connection between **Hadamard directional differentiability tangentially** to  $(\mathbb{G}, \mathbb{H})$  and **directional differentiability**.

## Proposition

Let  $f : \mathbb{D} \rightarrow \mathbb{R}^m$  be Hadamard directionally differentiable at  $x$  tangentially to  $(\mathbb{G}, \mathbb{H})$  and  $h \in \mathbb{T}(x; \mathbb{G}) \cap \mathbb{T}(x; \mathbb{H})$ .

Then, the function  $f$  is directionally differentiable at  $x$  in the direction  $h$  if and only if there is a  $\varepsilon_h > 0$  such that  $x + th \in A$  for all  $0 < t < \varepsilon_h$ .

In such a case, we have  $f'_+(x; h) = f'_H(x, h; \mathbb{G}, \mathbb{H})$ .

## Proposition

If a function  $f$  is Hadamard directionally differentiable at  $x$  tangentially to  $(\mathbb{G}, \mathbb{H})$  then  $f'_H(x, \cdot; \mathbb{G}, \mathbb{H})$  is a continuous function on  $\mathbb{T}(x; \mathbb{G}) \cap \mathbb{T}(x; \mathbb{H})$ .

# Hadamard differentiability tangentially to a set

We possess an equivalent definition.

- Function  $f$  is Hadamard directionally differentiable at  $x \in \mathbb{D}$  tangentially to  $(\mathbb{G}, \mathbb{H})$  if and only if  $f'_H(x, h; \mathbb{G}, \mathbb{H})$  exists for all  $h \in \mathbb{T}(x; \mathbb{G}) \cap \mathbb{T}(x; \mathbb{H})$  and

$$\lim_{\substack{t \rightarrow 0+ \\ \varepsilon \rightarrow 0+}} \sup_{\substack{h \in K, \|\xi\| \leq \varepsilon \\ x+t(h+\xi) \in \mathbb{G}}} \left\| \frac{1}{t} (f(x + t(h + \xi)) - f(x)) - f'_H(x, h; \mathbb{G}, \mathbb{H}) \right\| = 0$$

for all compacts  $K \subset \mathbb{T}(x; \mathbb{G}) \cap \mathbb{T}(x; \mathbb{H})$ .

# Contingent derivative of a set-valued mapping

Another difficulties arise, if  $f$  is a set-valued mapping between two topological vector spaces. Such a case appears very naturally, for instance in a stochastic optimization theory.

Let us consider an optimization problem

$$\varphi(x) = \max \{f(u; x) : u \in \mathcal{U}_x\}$$

depending on a parameter  $x \in \mathcal{X} \subset \mathbb{R}^p$ ,  $\mathcal{U}_x \subset \mathbb{R}^n$ . The set of all  $\varepsilon$ -optimal solutions

$$\psi(x; \varepsilon) = \{u \in \mathcal{U}_x : f(u; x) \geq \varphi(x) - \varepsilon\}, \varepsilon > 0$$

is of our interest. The mappings is naturally set-valued.

Considering set-valued mappings for purpose of Delta Theorem, one needs a generalization of Hadamard derivative. A convenient one is called contingent derivative and its definition can be found in any monograph on set-valued functions; e.g. in [1], [2].

# Contingent derivative of a set-valued mapping

$f : \mathbb{R}^n \rightarrow 2^{\mathbb{R}^m}$  be a set-valued function,  $x \in \mathbb{R}^n$  and  $y \in \mathbb{R}^m$ .

- ▶ Contingent derivative of  $f$  at  $(x, y)$  is defined as a set-valued function  $\nabla f(x, y; \cdot) : \mathbb{R}^n \rightarrow 2^{\mathbb{R}^m}$  with the property:

$$z \in \nabla f(x, y; h) \iff (0, h, z) \in \text{clo}(Df(x, y)),$$

where  $Df(x, y) = \{(t, h, z) : t > 0, h \in \mathbb{R}^n, y + tz \in f(x + th)\}$ .

# Contingent derivative of a set-valued mapping

The contingent derivative is connected with Hadamard directional differentiability tangentially to a set.

## Proposition

$G \subset D \subset \mathbb{R}^n$ ,  $H \subset \mathbb{R}^n$  and  $x \in D$ . Let a function  $f : D \rightarrow \mathbb{R}^m$  be Hadamard directionally differentiable at  $x$  tangentially to  $(G, H)$ . Define a set-valued function  $F : \mathbb{R}^n \rightarrow 2^{\mathbb{R}^m}$  such that

$$\begin{aligned} F(v) &= \{f(v)\} \text{ if } v \in G, \\ &= \emptyset \text{ if } v \notin G. \end{aligned}$$

Hence,

$$\begin{aligned} \nabla F(x, f(x); h) &= \{f'_H(x, h; G, H)\} \text{ if } h \in T(x; G) \cap T(x; H), \\ &= \emptyset \text{ whenever } y \neq f(x), \\ &= \emptyset \text{ whenever } h \notin T(x; G), y \in \mathbb{R}^m. \end{aligned}$$

# Limits in Kuratowski sense

For indexed sets  $A_t \subset \mathbb{R}^n$ ,  $t > 0$ , 'lim', 'limsup' and 'liminf' in Kuratowski sense are

$$K\text{-}\limsup_{t \rightarrow 0^+} A_t = \left\{ x \in \mathbb{R}^n : \begin{array}{l} \text{there is a sequence } a_{t_n} \in A_{t_n}, t_n > 0, \\ \lim_{n \rightarrow +\infty} t_n = 0, \quad \lim_{n \rightarrow +\infty} a_{t_n} = x \end{array} \right\},$$

$$K\text{-}\liminf_{t \rightarrow 0^+} A_t = \left\{ x \in \mathbb{R}^n : \begin{array}{l} \text{there is a selection } a_t \in A_t, t > 0, \\ \lim_{t \rightarrow 0^+} a_t = x \end{array} \right\}.$$

If both 'limits' coincide we speak about the **limit in Kuratowski sense** and set

$$K\text{-}\lim_{t \rightarrow 0^+} A_t = K\text{-}\limsup_{t \rightarrow 0^+} A_t = K\text{-}\liminf_{t \rightarrow 0^+} A_t.$$

Let us mention that all limits in Kuratowski sense are closed sets.

## An agreement:

$y \rightarrow x$  means that  $y$  tends to  $x$ ,

$y \rightarrow x+$  means that  $y$  tends to  $x$  and  $y > x$ ,

$y \rightarrow x-$  means that  $y$  tends to  $x$  and  $y < x$ ,

$y \rightarrow x^*$  means that  $y$  tends to  $x$  and  $y \neq x$ .

# Tangent cones

## Bouligand tangent cone

(also contingent cone, Bouligand contingent cone)

to  $A \subset \mathbb{R}^n$  at  $x \in \mathbb{R}^n$  is

$$\mathbb{T}(x; A) = \left\{ h \in \mathbb{R}^n : \begin{array}{l} \text{there is a sequence } a_n \in A, t_n > 0, \\ \lim_{n \rightarrow +\infty} t_n = 0, \lim_{n \rightarrow +\infty} \frac{1}{t_n}(a_n - x) = h \end{array} \right\}.$$

The Bouligand tangent cone is the **limsup in Kuratowski sense**

$$\mathbb{T}(x; A) = K\text{-}\limsup_{t \rightarrow 0+} \frac{1}{t}(A - x).$$

**Clarke tangent cone** to  $A \subset \mathbb{R}^n$  at  $x \in \mathbb{R}^n$  is

$$\mathbb{T}_C(x; A) = K\text{-}\liminf_{\substack{y \rightarrow x, y \in A \\ t \rightarrow 0+}} \frac{1}{t}(A - y).$$

# Normal cones

**Pre-normal cone** (also **Regular normal cone**, **Fréchet normals**) to  $A \subset \mathbb{R}^n$  at  $\mathbf{x} \in \mathbb{R}^n$  is

$$\widehat{N}(\mathbf{x}; A) = \left\{ \mathbf{h} \in \mathbb{R}^n : \begin{array}{l} \text{for each sequence } a_n \in A, a_n \neq \mathbf{x}, a_n \rightarrow \mathbf{x}, \\ \limsup_{n \rightarrow +\infty} \frac{\mathbf{h}^\top (a_n - \mathbf{x})}{\|a_n - \mathbf{x}\|} \leq 0 \end{array} \right\}.$$

For  $\varepsilon \geq 0$ ,

**Set of  $\varepsilon$ -normals** to  $A \subset \mathbb{R}^n$  at  $\mathbf{x} \in \mathbb{R}^n$  is

$$\widehat{N}_\varepsilon(\mathbf{x}; A) = \left\{ \mathbf{h} \in \mathbb{R}^n : \begin{array}{l} \text{for each sequence } a_n \in A, a_n \rightarrow \mathbf{x}, \\ \limsup_{n \rightarrow +\infty} \frac{\mathbf{h}^\top (a_n - \mathbf{x})}{\|a_n - \mathbf{x}\|} \leq \varepsilon \end{array} \right\}.$$

Of course,  $\widehat{N}_0(\mathbf{x}; A) = \widehat{N}(\mathbf{x}; A)$ .

# Normal cones

**Normal cone** to  $A \subset \mathbb{R}^n$  at  $x \in \mathbb{R}^n$  is

$$N(x; A) = K\text{-}\limsup_{\substack{y \rightarrow x \\ \varepsilon \rightarrow 0+}} \widehat{N}_\varepsilon(y; A).$$

If  $A$  is closed then

$$N(x; A) = K\text{-}\limsup_{y \rightarrow x} \widehat{N}(y; A).$$

# Tangent and Normal cones

Always,

$$\begin{aligned}
 \mathbb{T}_C(\mathbf{x}; A) &\subset \mathbb{T}(\mathbf{x}; A), \\
 \mathbb{N}(\mathbf{x}; A) &\supset \widehat{\mathbb{N}}(\mathbf{x}; A), \\
 \mathbf{v} \in \widehat{\mathbb{N}}(\mathbf{x}; A) &\iff \forall \mathbf{w} \in \mathbb{T}(\mathbf{x}; A) \quad \mathbf{v}^\top \mathbf{w} \leq 0, \\
 \mathbb{N}(\mathbf{x}; A) &= \mathbb{T}(\mathbf{x}; A)^*, \\
 \mathbb{N}(\mathbf{x}; A)^* &\supset \mathbb{T}(\mathbf{x}; A).
 \end{aligned}$$

Hence analogically, **Clarke normal cone is defined by**

$$\mathbb{N}_C(\mathbf{x}; A) = \mathbb{T}_C(\mathbf{x}; A)^*.$$

Clarke normal cone fulfills

$$\mathbb{N}_C(\mathbf{x}; A)^* = \mathbb{T}_C(\mathbf{x}; A).$$

# Tangent and Normal cones

For a convex set  $C \subset \mathbb{R}^n$

$$\begin{aligned}\mathbb{T}(\mathbf{x}; C) &= \text{clo}(\{\mathbf{w} \in \mathbb{R}^n : \exists \lambda > 0 \text{ such that } \mathbf{x} + \lambda \mathbf{w} \in C\}), \\ \mathbb{N}(\mathbf{x}; C) = \widehat{\mathbb{N}}(\mathbf{x}; C) &= \{\mathbf{v} \in \mathbb{R}^n : \forall \mathbf{c} \in C \quad \mathbf{v}^\top (\mathbf{c} - \mathbf{x}) \leq 0\}, \\ \widehat{\mathbb{N}}_\varepsilon(\mathbf{x}; C) &= \{\mathbf{v} \in \mathbb{R}^n : \forall \mathbf{c} \in C \quad \mathbf{v}^\top (\mathbf{c} - \mathbf{x}) \leq \varepsilon \|\mathbf{c} - \mathbf{x}\|\}.\end{aligned}$$

# Tangent and Normal cones

Let a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  be Hadamard differentiable at  $x \in \mathbb{R}^n$ . Then,

$$\mathbb{T}(x; \text{graph}(f)) = \left\{ \begin{pmatrix} \nabla f(x)^\top h \\ h \end{pmatrix} : h \in \mathbb{R}^n \right\},$$

$$\widehat{\mathbb{N}}(x; \text{graph}(f)) = \left\{ \begin{pmatrix} w \\ -\nabla f(x) w \end{pmatrix} : w \in \mathbb{R}^m \right\},$$

$$\mathbb{T}(x; \text{epi}(f)) = \left\{ \begin{pmatrix} y \\ h \end{pmatrix} : h \in \mathbb{R}^n, y \geq \nabla f(x)^\top h \right\},$$

$$\widehat{\mathbb{N}}(x; \text{epi}(f)) = \left\{ \begin{pmatrix} w \\ -\nabla f(x) w \end{pmatrix} : w \in \mathbb{R}^m, w \leq 0 \right\}.$$
